

# Understanding Generative Adversarial Networks (GAN)

**Group Meeting Discussion**

Friday, March 30, 2018

## 一个关于GAN的感性例子

假如你是一名**篮球运动员**，你想在下次**比赛**中得到**上场机会**。

于是在每一次**训练赛**之后你跟**教练**进行沟通：

- 你：教练，我想打球
- 教练：（评估你的**训练赛表现**之后）... 算了吧
- （你**通过**跟其他人比较，发现自己的运球很差，于是你苦练了一段时间）
- 你：教练，我想打球
- 教练：... 嗯 还不行
- （你**发现**大家**投篮**都很准，于是你苦练了一段时间的投篮）
- 你：教练，我想打球
- 教练：... 嗯 还有所欠缺
- （你**发现**你的身体不够壮，被人一碰就倒，于是你去泡健身房）

.....

通过这样不断的努力和被拒绝，你最终在某一次**训练赛**之后得到**教练**的**赞赏**，获得了**上场**的机会。

值得一提的是在**这个过程**中，所有的**候选球员**都在不断地**进步**和**提升**。因而**教练**也要不断地通过**对比**场上**球员**和**候补球员**来学习分辨哪些**球员**是真正可以**上场**的，并且要“**观察**”得比**球员**更**频繁**。随着大家的成长**教练**也会变得越**来越严格**。

# Background

- Generative adversarial networks (GANs) are (deep) neural net architectures comprised of two nets, pitting one against the other (thus the “adversarial”).
- [GANs were introduced in a paper](#) by Ian Goodfellow and other researchers at the University of Montreal, including Yoshua Bengio, in 2014.
- Referring to GANs, Facebook’s AI research director Yann LeCun [called adversarial training](#) “the most interesting idea in the last 10 years in ML.”
- GANs’ potential is huge, because they can learn to mimic any distribution of data. The number of papers about GAN is growing fast.

# The GANfather: The man who's given machines the gift of imagination

By pitting neural networks against one another, Ian Goodfellow has created a powerful AI tool. Now he, and the rest of us, must face the consequences.

by Martin Giles February 21, 2018

O

ne night in 2014, Ian Goodfellow went drinking to celebrate with a fellow doctoral student who had just graduated. At Les 3 Brasseurs (The Three Brewers), a favorite Montreal watering hole, some friends asked for his help with a thorny project they were working on: a computer that could create photos by itself.

Images source from the review

# Understanding GAN Framework

- A GAN can be trained to generate images from random noises. For example, we can train a GAN to generate digit images that look like hand-written digit images from MNIST database.
- A GAN has two parts in it: the generator that generates images and the discriminator that classifies real and fake images.

# GAN Framework - Generator

- The input to the generator is a series of randomly generated numbers called latent sample. Once trained, the generator can produce digit images from latent samples.

Our generator is a simple fully connected network that takes a latent sample (100 randomly generated numbers) and produces 784 data points which can be reshaped into a 28 x 28 digit image which is the size used by all MNIST digit images.

To train the generator, we need to train a GAN. Before talking about GAN, we shall discuss the discriminator.

# GAN Framework - Discriminator

- The discriminator is a classifier trained using the supervised learning. It classifies whether an image is real (1) or not (0).

We train the discriminator using both the MNIST images and the images generated by the generator. If the input image is from the MNIST database, the discriminator should classify it as real. If the input image is from the generator, the discriminator should classify it as fake.

# Training the GAN means Training the Generator

- We connect the generator and the discriminator to produce a GAN.

When we feed a latent sample to the GAN, the generator internally produces a digit image which is then passed to the discriminator for classification. If the generator does a good job, the discriminator returns a value close to 1 (high probability of the image being real).

We feed latent samples to the GAN while setting the expected outcome (label) to 1 (real) as we expect the generator to produce realistic image, and we expect the discriminator to say it is real or close to real.

However, the generator initially produces garbage images, and the loss value is high. So, the back-propagation updates the generator's weights to produce more realistic images as the training continues.

# How to train a GAN

- There is one catch in this process of training the generator via the GAN. We do not want the discriminator's weights to be affected because we are using the discriminator as merely a classifier.
- For this reason, we set the discriminator non-trainable during the generator training.

# Training Loop of a GAN

- To get a better generator, we also need to train the discriminator as well so that it can do a good job as a classifier of real and fake images. We train the discriminator and the generator in turn in a loop as follows:

- Step 1) Set the discriminator trainable;
- Step 2) Train the discriminator with the real MNIST digit images and the images generated by the generator to classify the real and fake images.
- Step 3) Set the discriminator non-trainable;
- Step 4) Train the generator as part of the GAN. We feed latent samples into the GAN and let the generator to produce digit images and use the discriminator to classify the image.

The loop should ideally continue until they are both trained well and can not be improved any further.

[Image source: Understanding Generative Adversarial Networks.](#)

## 1. The Discriminator Training

## 2. The Generator Training (via GAN)

# Training Loop of a GAN

- Prepare a batch of real images
- Prepare a batch of fake images generated by the generator using latent samples
- Make the discriminator trainable
- Train the discriminator to classify the real and fake images
- Make the discriminator non-trainable
- Train the generator via the GAN

## Stabilizing GAN

As it turns out, training a GAN is quite hard, and there are many tricks and heuristics required. It is because the discriminator and the generator are not cooperating and individually learning to predict better.

For example, the generator might learn to fool the discriminator with garbage. Ideally, the discriminator should learn earlier than the generator so that it can classify images accurately.

[Image source: Understanding Generative Adversarial Networks.](#)

Two different training results

# But does it actually work?

- The result of the simple GAN is not outstanding. Some of them look pretty good but others are not.

As it turns out, training a GAN requires lots of hacks as per [How to Train a GAN? Tips and tricks to make GANs work](#) such as label smoothing and other techniques.

“There are all sorts of empirical quirks. If I train the discriminator much faster than the generator, the generator gives up learning. In some case, the generator learns to deceive the discriminator and makes the discriminator unable to learn to classify properly.”

-- [Naoki Shibuya](#)

The results are not outstanding as we are using simple networks. Deep Convolutional GAN (aka DCGAN) would produce better results than this.

Testing results from **Generator**

# The Loss Function of a GAN

- $G(z)$ : Generator Network
- $D(x)$ : Discriminator Network
- $P_{data}(x)$ : the distribution of real data;
- $X$ : sample from  $P_{data}(x)$ .
- $P(z)$ : distribution of generator;
- $Z$ : sample from  $P_z(z)$ .
- $D(x)$ : discriminative distribution

- a) an adversarial pair near convergence.
- b)  $D$  is trained to discriminate samples from data.
- c) After an update to  $G$ .
- d) After several steps of training.

if  $G$  and  $D$  have enough capacity, they will reach a point at which both cannot improve.  
The discriminator is unable to differentiate between the two distributions, i.e.  $D(x) = \frac{1}{2}$ .

Image from : <https://www.analyticsvidhya.com/blog/2017/06/introductory-generative-adversarial-networks-gans/> ; GAN paper.

# The Loss Function of a GAN

$$\min_G \max_D V(D, G) = \mathbb{E}_{\mathbf{x} \sim p_{\text{data}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{\mathbf{z} \sim p_z(\mathbf{z})} [\log(1 - D(G(\mathbf{z})))].$$

- [Cross entropy](#):  $H(p, q) := -\sum_i p_i \log q_i$  where  $p$  and  $q$  denote a “true” and an “empirical/estimated” distribution.
- For one data point  $x_1$  and its label from a binary classification task, we get the following loss function, where here I’ve changed the input to be more precise:

One samples:

$$H((x_1, y_1), D) = -y_1 \log D(x_1) - (1 - y_1) \log(1 - D(x_1))$$

N samples:

$$H((x_i, y_i)_{i=1}^N, D) = -\sum_{i=1}^N y_i \log D(x_i) - \sum_{i=1}^N (1 - y_i) \log(1 - D(x_i))$$

Infinite samples ( $y_i = 1/2$ ):

$$H((x_i, y_i)_{i=1}^\infty, D) = -\frac{1}{2} \mathbb{E}_{x \sim p_{\text{data}}} [\log D(x)] - \frac{1}{2} \mathbb{E}_z [\log(1 - D(G(z)))]$$

# The Loss Function of a GAN (Cont.)

$$\min_G \max_D V(D, G) = \mathbb{E}_{\mathbf{x} \sim p_{\text{data}}(\mathbf{x})} [\log D(\mathbf{x})] + \mathbb{E}_{\mathbf{z} \sim p_z(\mathbf{z})} [\log(1 - D(G(\mathbf{z})))].$$

- Understanding the  $\min_G \max_D V(D, G)$ .
- $V(D, G)$  means the measurement of difference of  $\mathbf{x}$  and  $\mathbf{z}$ .
- $\max_D V(D, G)$  means fix the  $G$  and train the  $D$ .
- $\min_G L$  (where  $L = \max_D V(D, G)$ ) means fix  $D$  to train  $G$ . Minimize the different between  $\mathbf{x}$  and  $\mathbf{z}$ .

**Proposition 1.** For  $G$  fixed, the optimal discriminator  $D$  is

$$D_G^*(\mathbf{x}) = \frac{p_{\text{data}}(\mathbf{x})}{p_{\text{data}}(\mathbf{x}) + p_g(\mathbf{x})} \quad (2)$$

*Proof.* The training criterion for the discriminator  $D$ , given any generator  $G$ , is to maximize the quantity  $V(G, D)$

$$\begin{aligned} V(G, D) &= \int_{\mathbf{x}} p_{\text{data}}(\mathbf{x}) \log(D(\mathbf{x})) d\mathbf{x} + \int_{\mathbf{z}} p_z(\mathbf{z}) \log(1 - D(G(\mathbf{z}))) d\mathbf{z} \\ &= \int_{\mathbf{x}} p_{\text{data}}(\mathbf{x}) \log(D(\mathbf{x})) + p_g(\mathbf{x}) \log(1 - D(\mathbf{x})) d\mathbf{x} \end{aligned} \quad (3)$$

For any  $(a, b) \in \mathbb{R}^2 \setminus \{0, 0\}$ , the function  $y \rightarrow a \log(y) + b \log(1 - y)$  achieves its maximum in  $[0, 1]$  at  $\frac{a}{a+b}$ . The discriminator does not need to be defined outside of  $\text{Supp}(p_{\text{data}}) \cup \text{Supp}(p_g)$ , concluding the proof.  $\square$

**Proposition 2.** If  $G$  and  $D$  have enough capacity, and at each step of Algorithm 1, the discriminator is allowed to reach its optimum given  $G$ , and  $p_g$  is updated so as to improve the criterion

$$\mathbb{E}_{\mathbf{x} \sim p_{\text{data}}} [\log D_G^*(\mathbf{x})] + \mathbb{E}_{\mathbf{x} \sim p_g} [\log(1 - D_G^*(\mathbf{x}))]$$

then  $p_g$  converges to  $p_{\text{data}}$

*Proof.* Consider  $V(G, D) = U(p_g, D)$  as a function of  $p_g$  as done in the above criterion. Note that  $U(p_g, D)$  is convex in  $p_g$ . The subderivatives of a supremum of convex functions include the derivative of the function at the point where the maximum is attained. In other words, if  $f(x) = \sup_{\alpha \in \mathcal{A}} f_{\alpha}(x)$  and  $f_{\alpha}(x)$  is convex in  $x$  for every  $\alpha$ , then  $\partial f_{\beta}(x) \in \partial f$  if  $\beta = \arg \sup_{\alpha \in \mathcal{A}} f_{\alpha}(x)$ . This is equivalent to computing a gradient descent update for  $p_g$  at the optimal  $D$  given the corresponding  $G$ .  $\sup_D U(p_g, D)$  is convex in  $p_g$  with a unique global optima as proven in Thm 1, therefore with sufficiently small updates of  $p_g$ ,  $p_g$  converges to  $p_x$ , concluding the proof.  $\square$

# The Training Algorithm (GAN Paper)

---

**Algorithm 1** Minibatch stochastic gradient descent training of generative adversarial nets. The number of steps to apply to the discriminator,  $k$ , is a hyperparameter. We used  $k = 1$ , the least expensive option, in our experiments.

---

**for** number of training iterations **do**

**for**  $k$  steps **do**

- Sample minibatch of  $m$  noise samples  $\{\mathbf{z}^{(1)}, \dots, \mathbf{z}^{(m)}\}$  from noise prior  $p_g(\mathbf{z})$ .
- Sample minibatch of  $m$  examples  $\{\mathbf{x}^{(1)}, \dots, \mathbf{x}^{(m)}\}$  from data generating distribution  $p_{\text{data}}(\mathbf{x})$ .
- Update the discriminator by ascending its stochastic gradient:

$$\nabla_{\theta_d} \frac{1}{m} \sum_{i=1}^m \left[ \log D(\mathbf{x}^{(i)}) + \log \left( 1 - D(G(\mathbf{z}^{(i)})) \right) \right].$$

**end for**

- Sample minibatch of  $m$  noise samples  $\{\mathbf{z}^{(1)}, \dots, \mathbf{z}^{(m)}\}$  from noise prior  $p_g(\mathbf{z})$ .
- Update the generator by descending its stochastic gradient:

$$\nabla_{\theta_g} \frac{1}{m} \sum_{i=1}^m \log \left( 1 - D(G(\mathbf{z}^{(i)})) \right).$$

**end for**

The gradient-based updates can use any standard gradient-based learning rule. We used momentum in our experiments.

---

## Wasserstein GAN

Martin Arjovsky, Soumith Chintala, Léon Bottou

(Submitted on 26 Jan 2017 (v1), last revised 6 Dec 2017 (this version, v3))

We introduce a new algorithm named WGAN, an alternative to traditional GAN training. In this new model, we show that we can improve the stability of learning, get rid of problems like mode collapse, and provide meaningful learning curves useful for debugging and hyperparameter searches. Furthermore, we show that the corresponding optimization problem is sound, and provide extensive theoretical work highlighting the deep connections to other distances between distributions.

"mode collapse comes from the fact that the optimal generator for a fixed discriminator is a sum of deltas on the points the discriminator assigns the highest values, as brilliantly observed by [11]"

This was actually known since the first GAN paper. I don't think [11] claim identifying this as a contribution. Their solution to that problem is very nice though.

You can see this claim in my slides, for example these: <http://www.iangoodfellow.com/slides/2016-08-31-Berkeley.pdf>

"Fully optimizing the generator with the discriminator held constant results in mapping all points to the argmax of the discriminator"

It's worth mentioning that, depending on the structure of the discriminator, the set of points defining the argmax might not be isolated deltas, so the description in this paper isn't quite correct.

Figure 5: Algorithms trained with a DCGAN generator. Left: WGAN algorithm. Right: standard GAN formulation. Both algorithms produce high quality samples.

Figure 6: Algorithms trained with a generator without batch normalization and constant number of filters at every layer (as opposed to duplicating them every time as in [18]). Aside from taking out batch normalization, the number of parameters is therefore reduced by a bit more than an order of magnitude. Left: WGAN algorithm. Right: standard GAN formulation. As we can see the standard GAN failed to learn while the WGAN still was able to produce samples.

Figure 7: Algorithms trained with an MLP generator with 4 layers and 512 units with ReLU nonlinearities. The number of parameters is similar to that of a DCGAN, but it lacks a strong inductive bias for image generation. Left: WGAN algorithm. Right: standard GAN formulation. The WGAN method still was able to produce samples, lower quality than the DCGAN, and of higher quality than the MLP of the standard GAN. Note the significant degree of mode collapse in the GAN MLP.

## Improved Training of Wasserstein GANs

Ishaan Gulrajani, Faruk Ahmed, Martin Arjovsky, Vincent Dumoulin, Aaron Courville

(Submitted on 31 Mar 2017 (v1), last revised 25 Dec 2017 (this version, v3))

Generative Adversarial Networks (GANs) are powerful generative models, but suffer from training instability. The recently proposed Wasserstein GAN (WGAN) makes progress toward stable training of GANs, but sometimes can still generate only low-quality samples or fail to converge. We find that these problems are often due to the use of weight clipping in WGAN to enforce a Lipschitz constraint on the critic, which can lead to undesired behavior. We propose an alternative to clipping weights: penalize the norm of gradient of the critic with respect to its input. Our proposed method performs better than standard WGAN and enables stable training of a wide variety of GAN architectures with almost no hyperparameter tuning, including 101-layer ResNets and language models over discrete data. We also achieve high quality generations on CIFAR-10 and LSUN bedrooms.

Every week, new GAN papers are coming out and it's hard to keep track of them all, not to mention the incredibly creative ways in which researchers are naming these GANs! So, here's a list of what started as a fun activity compiling all named GANs!

(S-Z)

Figure 1: DCGAN generator used for LSUN scene motion  $Z$  is projected to a small spatial extent convolution. A series of four fractionally-strided convolutions (in series) and deconvolutions (in series) then convert this high level representation into a fully connected or pooling layers are used.

Figure 3: Generated bedrooms after five epochs of training. There appears to be evidence of visual under-fitting via repeated noise textures across multiple samples such as the base boards of some of the beds.

Fig. 1. We use generative adversarial networks (GAN) [12] to perform on the natural image manifold. We first project an original photo  $I$  to a low-dimensional latent vector  $z_0$ . We then use an interactive image editing UI to modify the color and shape of the object (for example, dragging the object to change its geometric and color change). This process is controlled by our interactive image editing UI.

This bird has a yellow belly and black tarsus, grey back, white wings, and brown throat, nape with a black face

with a  $64 \times 64$  input image  $I$  from our factor of two (red arrow) to produce a new version  $I_0$  of  $I$ ; (iii) with equal discriminative model  $D_0$ . In the real  $D_0$  that computes the probability of a generated image  $I_0$  receives as input  $\tilde{I}_0 = G_0(z_0, I_0)$ , which is input to Optimizing Eqn. 2.  $G_0$  thus learns to produce image  $I_0$ . The same procedure is repeated for the next level. At each level are trained independently. At the final level, standard GANs  $G_3$  &  $D_3$ .
